II. Dependencies

"Explicitly declare and isolate dependencies"

II. Dependencies

What is a packaging system?

- A packaging system is a collection of software tools that automate the process of installing, upgrading, configuring, and removing dependencies for an application in a consistent manner.
- A package manager deals with packages as archive files. Packages
 contain metadata, such as their name, description of their purpose, version
 number, checksum, and a list of other dependencies necessary for the
 package to work properly.
- Packaging systems usually provide two main roles: **dependency declaration** and **dependency isolation** which must always co-exist and be used together.
